22 TROUBLESHOOTING

23 VERSION HISTORY

CHALLENGES

Rubrik was founded in 2014 to reinvent the data management software space which had not seen transformative innovation in 20 plus years. At that time the company was focused on all things modern - virtualization, cloud, APIs, DevOps, containers, etc... As the company grew, customers also asked Rubrik to take it's simple and elegant design to other areas of the data center including databases (SQL Server, Oracle), NAS shares, and physical servers (Windows, Linux, AIX, Solaris).

VMware ESX 1.0 was released nearly 20 years ago but believe it or not there are still many physical servers still standing (mainly due to performance requirements) that need to be managed.¹ Part of managing these physical assets is, of course, standard backup and recovery of the data residing on those servers. Before the era of virtualization, backup and recovery software vendors provided the ability to perform restores of the operating systems to similar or dissimilar hardware platforms using a feature called "bare metal restore" or BMR.

Supporting BMR is challenging for software companies. Some of the issues include:

- Finding the right version of the OS
- Re-applying patches to the correct level
- Finding and reinstalling drivers for specific hardware
- Reinstalling the backup agent
- Remembering the disk partitioning configurations and recreating them

Instead of writing their own software to support BMR, many backup software vendors partnered or acquired technologies - (VERITAS Software made the acquisition of a company called The Kernel Group (TKG)² earlier in 2002 for its bare metal capabilities while EMC acquired a company called Indigo Stone in 2007 for its HomeBase BMR software.³

Even today many modern companies today are partnering with 3rd-party companies to address this gap in their software portfolios. Partnering with others is one way to solve the BMR problems but these technologies generally require separate management consoles, doubling the number of agents on the hosts, bloating the size of a single agent, and most importantly consuming more disk storage as the BMR images are usually separate from the "normal" backup images.

RUBRIK'S BMR DESIGN AND PROCESS FLOW

Rubrik's maniacal desire to simplify what was once extremely complex in legacy backup and recovery software is everywhere within the product line:

- Eliminating storage configuration complexity
- Increase operational efficiency by using software to automate the scheduling and retention of backups via Rubrik's SLA Domain Policies⁴
- Managing data replication and archival to cloud
- Google-like search functionality
- Simplifying restores using Instant Recovery

3 <https://www.crn.com/news/storage/199400218/emc-adds-bare-metal-recovery-by-acquiring-indigo-stone.htm>

4 <https://www.rubrik.com/blog/rubrik-sla-domain-settings-ops/>

To address these challenges of BMR for Linux, Rubrik looked towards the open source project [Relax-and-Recover](https://github.com/rear/rear)⁵ (ReaR⁶). The approach the Relax-and-Recover project took fits well with Rubrik's design philosophy. It allows for:

- Restore to dissimilar hardware: The product should support restores from one hardware platform to another.
- Remove the requirement and reliance of costly 3rd-party software (3rd party meaning another software company, non-open source).

The Rubrik CDM integration with Relax and Recover allows Rubrik Cloud Data Management (CDM) to perform bare metal recovery of Linux systems that are supported by Relax-and-Recover. This is done by including the installed Rubrik CDM Rubrik Backup Service (RBS) connector files in the bootable image that is created by Relax-and-Recover. Relax-and-Recover itself works by producing a bootable image of a Linux system's operating system. When the recovery system is booted from this image, it can repartition the target disks. Once that is done it initiates a restore from backup. Restores to different hardware are also possible, which can enable migrations.

At a high level Linux servers (physical and virtual) are protected at a file level by installing RBS on them. In this example the `/` and `/data` file systems are being protected. These file system level backups share the same characteristics as other Rubrik backup object types, incremental-forever backup approach, search/indexing, Instant Recovery/Live Mount, etc...

5 <https://github.com/rear/rear>

6 <http://relax-and-recover.org/>

If this server is unable to boot and needs to be recovered at the bare metal level, a bootable image needs to be created. This is done by installing Relax-and-Recover along with the Rubrik RBS connector (step 1). After installing Relax-and-Recover its configuration file is updated to specify that Rubrik CDM is the backup software. The Rubrik integration with Relax-and-Recover causes it to include RBS in the bootable image. This allows the recovery system to access Rubrik CDM during restore. After the configuration file is updated, the command `rear -v mkrescue` is run to create a bootable image (step 2). The `-v` option is used to see the verbose output and troubleshoot any errors.

Once the `rear -v mkrescue` command is working properly it can be scheduled to run regularly in cron or via the Rubrik software as a pre-command to the backup (step 3). Having the bootable image file created by the Rubrik CDM fileset pre-process step guarantees that any changes to the operating system are stored in the backups. Scheduling the boot image creation outside of Rubrik CDM, especially on a non-daily basis may result in the boot image not being current.

By default `rear -v mkrescue` saves the ISO file to `/var/lib/rear/output/rear-<hostname>.iso`. Rubrik CDM will backup the ISO file from this location as part of a regular fileset backup. Alternatively the ISO file can be stored in another location that is easy to access.

When it is time to recover the Linux server, either back to the same hardware or to new hardware, verify that the recovery system has a compatible disk layout with the Linux system that is being restored to it. See the Relax-and-Recover [Layout configuration](#)⁷ page for more details. Next burn the bootable image to boot media that is supported by the recovery system (step 4). The boot image can be recovered from Rubrik CDM by searching the Linux system's backups if it was previously included in its fileset. Otherwise a copy of the bootable image will need to be obtained from whatever storage location it was saved to.

The recovery system is booted using the newly created boot media (step 5). Once it is running the command `rear recover` is run on the recovery system (step 6). This command allows the parameters necessary to run the Rubrik RBS connector to be entered. It then starts the Rubrik RBS connector. After starting RBS, the `rear recover` command repartitions the recovery system's disk to match what was on the original Linux server. Once the recovery system is repartitioned the `rear recover` command requests that the operator recover the file system data from Rubrik CDM. The operator then returns to the Rubrik console and performs an export of any data to restore, including the `/` file system. The export is redirected to the `/mnt/local` directory on the recovery system⁸. This directory points to the repartitioned file system(s) on the recovery system. If the original hardware is being restored to the export is performed directly. If the recovery system is not replacing the original Linux system the export is redirected to the new recovery system.

Once the export process finishes on Rubrik CDM, return to the recovery system and exit the `rear recover` command prompt (step 8). At this point Relax-and-Recover will fix the operating system file permissions and set up the bootloader. When the process finishes the recovery system is rebooted (step 9). Upon reboot the Linux system will be recovered and ready for use.

Note: Care should be taken in this setup with the recovered Linux system's networking. If static IP addresses were used the original IP address will be configured. This will cause a conflict if the original Linux system is still running. Booting the recovered Linux system in isolation and changing its IP address is advisable. Another issue may occur if DHCP was being used on the original Linux system and it was restored to new hardware. The MAC address of the recovered Linux system will have changed from the original causing it to get a new IP address. Any systems needing to access the recovered Linux system will need to use this new IP address.

⁷ <https://github.com/rear/rear/blob/master/doc/user-guide/06-layout-configuration.adoc>

⁸ While booted from the bootable media the `/` file system on the recovery system points to the bootable media.

LINUX BMR: A STEP-BY-STEP INSTRUCTION GUIDE

INSTALLATION

At this time the only version of Relax-and-Recover that supports Rubrik CDM is in the master branch of the Relax-and-Recover project. That can be found here: <https://github.com/rear/rear>. Once the next release of Relax-and-Recover is produced the regular OS package installers can be used to install Relax-and-Recover with support for Rubrik CDM. This process is described in the [Relax-and-Recover project website](#)⁹. In the meantime the Relax-and-Recover is installed by running the *make install* command from within the cloned project directory.

1. Install the Rubrik RBS Agent as directed by the Rubrik Users Guide.

CentOS Example:

Run `curl -kLOJ https://<rubrik_node_ip>/connector/rubrik-agent.x86_64.rpm`

```
[root@rear-cdm ~]# mkdir rubrik
[root@rear-cdm ~]# cd rubrik
[root@rear-cdm rubrik]# curl -kLOJ https://[REDACTED]/connector/rubrik-agent.x86_64.rpm
 % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 69.2M    0 69.2M    0     0  13.7M      0  --:--:--  0:00:05 --:--:-- 14.7M
```

Run `rpm -ihv rubrik-agent.x86_64.rpm`

```
[root@rear-cdm rubrik]# rpm -ihv rubrik-agent.x86_64.rpm
Preparing...                               ##### [100%]

⁹ <https://relax-and-recover.org/>

2. Clone the Rear Project

Get the URL for the project:

Run `git clone https://github.com/rear/rear.git`

```
[root@rear-cdm ~]# git clone https://github.com/rear/rear.git
Cloning into 'rear'...
remote: Enumerating objects: 191, done.
remote: Counting objects: 100% (191/191), done.
remote: Compressing objects: 100% (136/136), done.
remote: Total 46134 (delta 80), reused 47 (delta 17), pack-reused 45943
Receiving objects: 100% (46134/46134), 8.57 MiB | 8.74 MiB/s, done.
Resolving deltas: 100% (22336/22336), done.
```

3. Install Relax-and-Recover

Run `cd rear`

Run `make install`

```

[root@rear-cdm rear]# make install
== Validating scripts and configuration ==
find etc/ usr/share/rear/conf/ -name '*.conf' | xargs -n 1 bash -n
bash -n usr/sbin/rear
find . -name '*.sh' | xargs -n 1 bash -O extglob -O nullglob -n
find usr/share/rear -name '*.sh' | grep -v -E '(lib|skell|conf)' | while read FILE ; do \
    num=$(echo ${FILE##*/} | cut -c1-3); \
    if [[ "$num" = "000" || "$num" = "999" ]]; then \
        echo "ERROR: script $FILE may not start with $num"; \
        exit 1; \
    else \
        if $( grep '[_[:alpha:]]' <<< $num >/dev/null 2>&1 ) ; then \
            echo "ERROR: script $FILE must start with 3 digits"; \

```

CONFIGURATION

1. Edit `/etc/rear/local.conf` and enter:

```
# Sets output to an be an ISO file
OUTPUT=ISO
```

```
# Specifies CDM as the backup and recovery application
BACKUP=CDM
```

```
[root@rear-cdm ~]# cat /etc/rear/local.conf
# Default is to create Relax-and-Recover rescue media as ISO image
# set OUTPUT to change that
# set BACKUP to activate an automated (backup and) restore of your data
# Possible configuration values can be found in /usr/share/rear/conf/default.conf
#
# This file (local.conf) is intended for manual configuration. For configuration
# through packages and other automated means we recommend creating a new
# file named site.conf next to this file and to leave the local.conf as it is.
# Our packages will never ship with a site.conf.
OUTPUT=ISO
BACKUP=CDM
```

2. Optionally redirect the ISO file to a directory other than `/var/lib/rear/output`.

```
# Default "local" ISO directory (usually /var/lib/rear/output). However, to avoid
# duplicate ISO images when also using the OUTPUT_URL variable with a file syntax, it is
# then better only to use ISO_DIR. Keep in mind that ISO_DIR works only with an absolute
# directory path and does not replace OUTPUT_URL which supports the NETFS syntax
# (to copy the ISO image across the network).
ISO_DIR=$VAR_DIR/output
```

3. To have Rubrik CDM create a create ISO during each backup, create or configure a fileset backup with the following properties:

- a. Include at least the root (`/`) filesystem
- b. Enable Pre/Post scripts.
- c. Add `/usr/sbin/rear -v mkrescue` as the ***Pre-Backup script path***.
- d. It is highly recommended to select ***Cancel Backup if Pre-Backup Script Fails***. This will ensure that notifications are sent if the `rear -v mkrescue` command fails, instead of the backup failing silently.

Edit Fileset

Fileset Name
All Files with ReaR

Array Snapshots

Rules ⓘ

Use ****** to include all files

Include (/usr/local, *.pdf)

Exclude (/usr/local/temp, *.mov, *.mp3, *.mp4)

Do Not Exclude (/company, *.mp4)

Follow Network Shares

Enable Pre/Post Scripts

Pre-Backup Script Path

`/usr/sbin/rear -v mkrescue`

Cancel Backup if Pre-Backup Script Fails

BACKUP

1. Before running scheduled backups using Relax-and-Recover, first make sure that an ISO can be made using the `rear -v mkrescue` command. By default this command will create an ISO file called `/var/lib/rear/output/rear-<hostname>.iso`. If the `rear -v mkrescue` command fails, errors can be found in `/var/log/rear/rear-<hostname>.log`.

NOTE: See the [Troubleshooting](#) section if problems occur. Also refer to the [Relax-and-Recover Troubleshooting](#)¹⁰ page for other troubleshooting tips.

¹⁰ <https://github.com/rear/rear/blob/master/doc/user-guide/08-troubleshooting.adoc>

```

[root@rear-cdm ~]# rear -v mkrescue
Relax-and-Recover 2.5 / Git
Running rear mkrescue (PID 13975)
Using log file: /var/log/rear/rear-rear-cdm.log

Exiting rear mkrescue (PID 13975) and its descendant processes ...
Running exit tasks

```

2. Once the `rear -v mkrescue` command runs successfully scheduled backups of the system can be run.

RECOVERY

Currently the Rubrik CDM integration with Relax-and-Recover supports recovering to the original server and recovering to a new server. It also supports Linux systems with static IP addresses or DHCP IP addresses. Only interactive recovery is supported at this time.

PREREQUISITES

1. **IP Address assignment**

Before starting the recovery process verify how the IP addresses will be handled on the recovery system. If the original Linux system used static IP addresses, the recovery system will boot with this same IP address. If the original Linux system is being replaced and is down this may be fine. However, if the original Linux system is still running with the same static IP address the recovery system will need to be booted in isolation at first. While in isolation there will be an opportunity to change the static IP address to something new.

If DHCP addresses were used on the original Linux system a new IP address will be assigned to the recovery system. No IP address conflict should occur.

2. Boot image

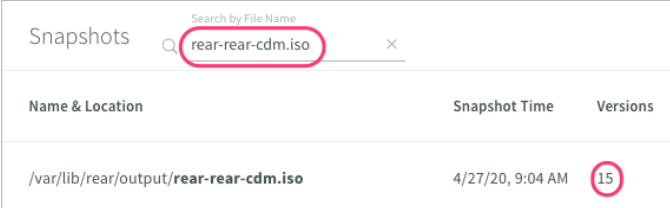

A copy of the boot image that was created by Relax-and-Recover will be needed to execute the steps below.

3. Hardware

Recovery to dissimilar hardware is supported. The disk layout and capacities must match or exceed the original Linux system though. See the Relax-and-Recover [Layout configuration](#)¹¹ page for more details.

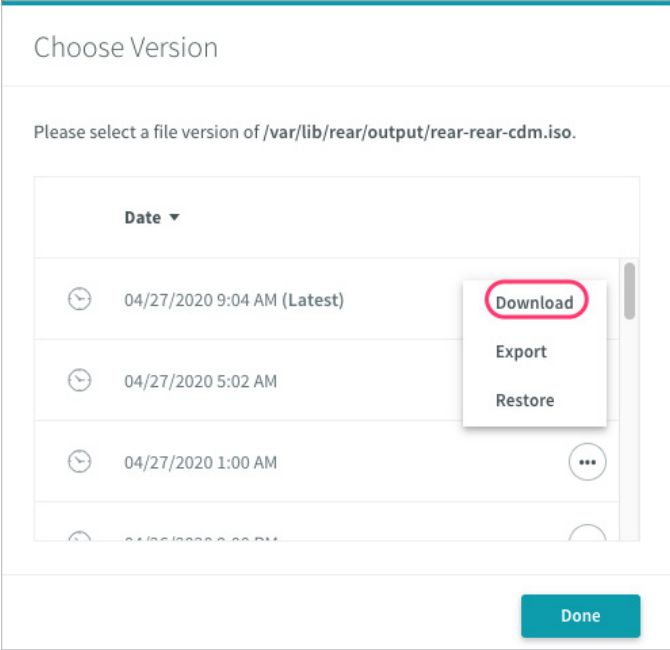

BOOTING THE RECOVERY SYSTEM

1. To begin the recovery process first obtain a copy of the recovery image.
 - a. Typically this will be `rear-<hostname>.iso` which was saved in `/var/lib/rear/output/` on the protected system unless the default options have been changed.
 - b. This file can be downloaded from a Rubrik fileset backup if it was protected as part of the filesystem data.

The screenshot shows a search interface with a search bar containing 'rear-rear-cdm.iso'. Below the search bar is a table with columns 'Name & Location', 'Snapshot Time', and 'Versions'. The table contains one entry: '/var/lib/rear/output/rear-rear-cdm.iso' with a snapshot time of '4/27/20, 9:04 AM' and a version number '15' circled in red.

Name & Location	Snapshot Time	Versions
/var/lib/rear/output/rear-rear-cdm.iso	4/27/20, 9:04 AM	15

The screenshot shows a 'Choose Version' dialog box. It prompts the user to select a file version of '/var/lib/rear/output/rear-rear-cdm.iso'. A dropdown menu is open, showing a list of versions with their dates and times. The 'Download' button is circled in red.

Please select a file version of `/var/lib/rear/output/rear-rear-cdm.iso`.

Date
04/27/2020 9:04 AM (Latest)
04/27/2020 5:02 AM
04/27/2020 1:00 AM

Buttons: Download, Export, Restore, Done

c. This file may have been stored externally as well.

2. Burn the `rear-<hostname>.iso` file to a bootable media that is compatible with the recovery system.
3. Boot the recovery system using the bootable media that was created from the `rear-<hostname>.iso` file.

¹¹ <https://github.com/rear/rear/blob/master/doc/user-guide/06-layout-configuration.adoc>

4. Select **Automatic Recover <hostname>** from the Relax-and-Recover boot menu.
 - a. This option automatically logs into the recovery system and runs rear recover.
 - b. Selecting Recover <hostname> will present a login prompt.
 - i. Enter any username (usually root).
 - ii. This will present a command prompt. Run any commands needed before starting recovery.
 1. In some cases stopping the Linux firewall is needed in this step.
 - iii. Run `rear recover`.
5. Recovering from the same Rubrik CDM cluster as the backup was performed is supported. Recovering from a Rubrik CDM cluster where the backup was replicated too is also supported. Recovering from the replica is useful for disaster recovery scenarios or migration where recovery to another datacenter is required.

Indicate if you are recovering from the same Rubrik CDM cluster or a different one.

 - a. If recovering from the same Rubrik cluster enter 'y'.

```

Configuring Relax-and-Recover rescue system

Running 00-functions.sh...

Running 65-sysctl.sh...
Running 99-makedev.sh...

Relax-and-Recover rescue system is ready

Launching 'rear recover' automatically

Relax-and-Recover 2.5 / Git
Running rear recover (PID 594)
Using log file: /var/log/rear/rear-rear-cdm.log
Running workflow recover within the ReaR rescue/recovery system

Is the data being restored from the original CDM Cluster? (y/n)
(default 'y' timeout 300 seconds)
n
Enter one of the IP addresses for the replica CDM cluster:
[REDACTED]
Replica Rubrik (CDM) cluster certificate installed.
```

6. Indicate if the same IP address is being used on the recovery server as on the original Linux server.

- a. Enter 'y' if the IP address of the recovery system is the same as the original Linux system.

```
Found the following IP addresses on this system:
inet [REDACTED]
inet6 [REDACTED]
inet6 [REDACTED]
inet6 [REDACTED]

Does this client have the same IP address as the original? (y/n)
(default 'y' timeout 300 seconds)
y
Rubrik (CDM) RBS agent started.
```

- b. Enter 'n' if the IP address of the recovery system is different from the original Linux system. The recovery system's unique Rubrik ID will be regenerated so that it does not conflict with the original Linux host.

```

Found the following IP addresses on this system:
inet [REDACTED]
inet6 [REDACTED]
inet6 [REDACTED]
inet6 [REDACTED]

Does this client have the same IP address as the original? (y/n)
(default 'y' timeout 300 seconds)
n
Rubrik (CDM) RBS agent now has new UUID.
Rubrik (CDM) RBS agent started.

```

7. Follow the prompts to properly repartition the recovery system's disks. If failures occur on this step see the Relax-and-Recover [Layout configuration](#)¹² and the [Relax-and-Recover Troubleshooting](#)¹³ pages for troubleshooting tips.

```

Comparing disks
Device sda has expected (same) size 17179869184 bytes (will be used for 'recover')
Disk configuration looks identical
Proceed with 'recover' (yes) otherwise manual disk layout configuration is enforced
(default 'yes' timeout 30 seconds)
y
User confirmed to proceed with 'recover'
Start system layout restoration.
Disk '/dev/sda': creating 'msdos' partition table
Disk '/dev/sda': creating partition number 1 with name 'primary'
Disk '/dev/sda': creating partition number 2 with name 'primary'
Creating LVM PV /dev/sda2
Restoring LVM VG 'centos'
Sleeping 3 seconds to let udev or systemd-udev create their devices...
Creating filesystem of type xfs with mount point / on /dev/mapper/centos-root.
Mounting filesystem /
Creating filesystem of type xfs with mount point /boot on /dev/sda1.
Mounting filesystem /boot
Creating swap on /dev/mapper/centos-swap
Disk layout created.
Please start the restore process on the Rubrik (CDM) cluster.

Register the appropriate IP address from this list with Rubrik (CDM):
inet [REDACTED]
inet6 [REDACTED]
inet6 [REDACTED]
inet6 [REDACTED]

Make sure all required data is restored to /mnt/local .

Next type 'exit' to continue the recovery.
Info: You can check the recovery process i.e. with the command 'df'.

rear>

```

8. When the `rear>` prompt appears, go to the Rubrik UI.

¹² <https://github.com/rear/rear/blob/master/doc/user-guide/06-layout-configuration.adoc>

¹³ <https://github.com/rear/rear/blob/master/doc/user-guide/08-troubleshooting.adoc>

RECOVER DATA

1. If the recovery system is using a different IP address than the original Linux system it must be registered in Rubrik CDM. Add a new Linux host using the Rubrik CDM GUI. Use the IP address of the recovery system if it is not in DNS or it's hostname if it is in DNS. There is no need to download and install the RBS client. It was already included in the Relax-and-Recover boot image.

Add Hosts

A Rubrik Backup Service must be installed on the hosts. Please enter comma separated IP addresses or hostnames to connect hosts. The existing Linux and Unix hosts will be pre-populated when you type the IP addresses or hostnames. The registered Oracle user can be overwritten in order to connect hosts. Compatible with:

Linux (**rpm** or **deb**)

- RHEL 6, 7
- CentOS 6, 7
- Oracle Linux 6, 7
- Ubuntu 14.04 LTS, 16.04 LTS, 17.04
- Debian Linux 8
- SUSE Linux 11, 12

AIX (**6.1, 7.1** or **7.2**)

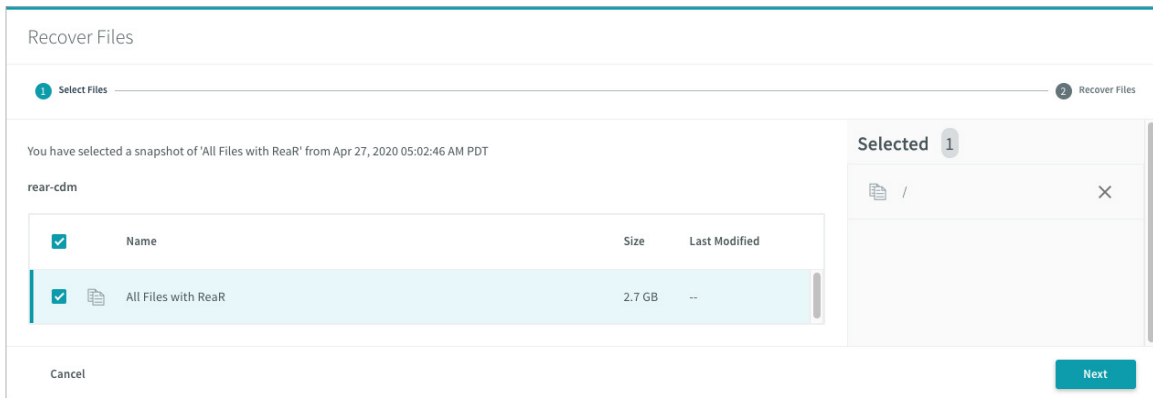

Solaris (**10, 11.1, 11.2, 11.3**)

IPs or Hostnames (Use commas to separate)

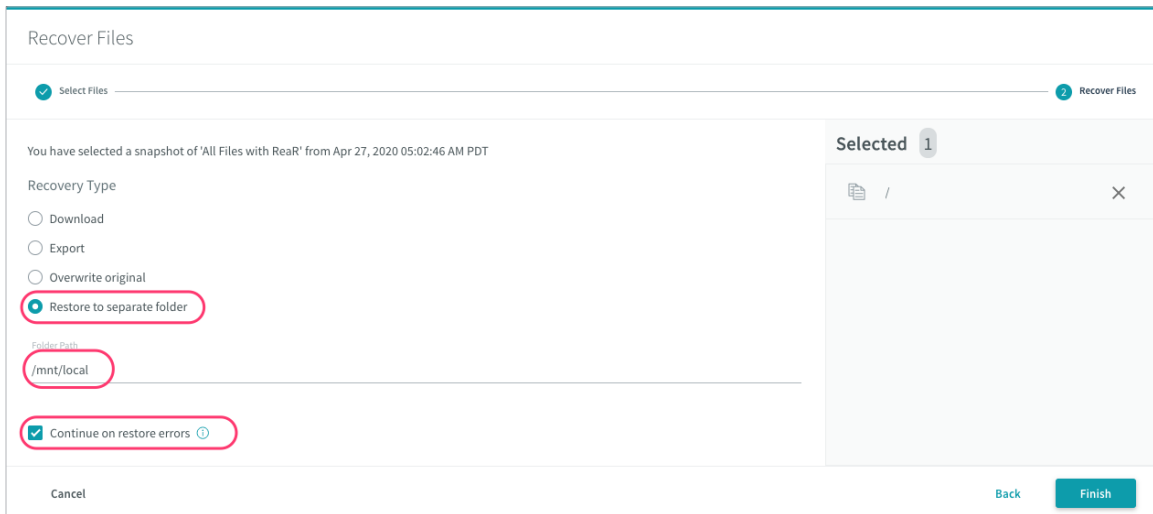

Cancel Add

2. Perform a Recover Files of at least the root file system for the original Linux system. All of the data for the Linux system can also be recovered in this step. The recovery needs to be redirected to `/mnt/local` as this is where the disks were mounted on the recovery system. The `/` (root) file system on the recovery system is from the boot media.

Snapshots		Search by File Name	
Today	Year	Month	Day
< April 21, 2020 >			
	12:25 AM		All Files wi... 39017 Files

	8:30 PM		All Files wi... 39017 Files Recover Files

- a. If the recovery system is using the IP address of the original Linux system do the following:
 - i. Select **Restore to separate folder**.
 - ii. Enter `/mnt/local` for **Export Path**.
 - iii. Select **Continue on restore errors**.

- b. If the recovery recovery system is using a different IP address than the original Linux system do the following:
 - i. Select **Export**.
 - ii. Select the hostname or IP address of the recovery system.
 - iii. Enter `/mnt/local` for **Export Path**
 - iv. Select **Ignore export errors**

Download Server Logs OK

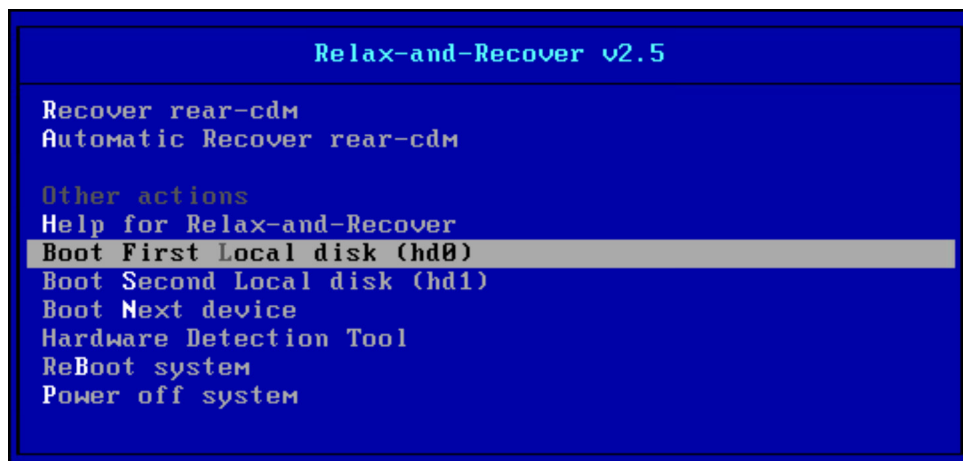

3. Once Rubrik CDM finishes recovering the data return to the recovery system and type `exit` at the `rear>` prompt.
4. Enter 'y' at the restore completion prompt question
5. Relax-and-Recover will do some housekeeping like fixing the root file system permissions and setting up the bootloader.
6. Once the prompt returns, gracefully reboot the system by selecting '3'.

```
rear> exit
Has the restore been completed and are you ready to continue the recovery? y
exit
Recreating directories (with permissions) from /var/lib/rear/recovery/directories_permissions_owner_group
Migrating disk-by-id mappings in certain restored files in /mnt/local to current disk-by-id mappings ...
Migrating network configuration files according to the mapping files ...
Running mkinitrd...
Updated initrd with new drivers for kernel 3.10.0-1062.4.1.el7.x86_64.
Running mkinitrd...
Updated initrd with new drivers for kernel 3.10.0-1062.el7.x86_64.
Skip installing GRUB Legacy boot loader because GRUB 2 is installed (grub-probe or grub2-probe exist).
Installing GRUB2 boot loader...
Determining where to install GRUB2 (no GRUB2_INSTALL_DEVICES specified)
Found possible boot disk /dev/sda - installing GRUB2 there
Finished 'recover'. The target system is mounted at '/mnt/local'.
Exiting rear recover (PID 595) and its descendant processes ...
Running exit tasks

'rear recover' finished successfully

1) View Relax-and-Recover log file(s)  3) Reboot
2) Go to Relax-and-Recover shell
Select what to do 3_
```

7. If the Relax-and-Recover boot loader starts, select the correct hard drive to boot from.

8. Allow the system to boot normally and it will be restored.
9. Eject the boot media from the restored Linux system.

KNOWN ISSUES

The following are known to be issues at the time of this writing:

- Until Relax-and-Recover v2.6 has been released and downstream package installers created follow the instructions in note 3 below to install rear from the <https://github.com/rear/rear> project page¹⁴ using `make install`.
 - Package installers can be made from the master branch by following [these instructions](#)¹⁵.
 - The `make install` process may fail with missing packages on a given system. Install the missing packages and try again. For example a basic Ubuntu installation needs to also have the `isolinux`, `binutils`, `genisoimage` and `syslinux` packages installed.
- Recovery via IPv6 is not yet supported.
- Automatic recovery from replica CDM cluster is not supported
- Rubrik CDM may take some time to recognize that the IP address has moved from one system to another. When restoring using the same IP, give Rubrik CDM up to 10 minutes to recognize that the agent is running on another machine. This usually comes up during testing when the original machine is shutdown but not being restored to.
- Recovery from a Rubrik CDM replication target cluster is only supported with CDM v4.2.1 and higher.
- Care must be taken with SUSE systems on DHCP. They tend to request the same IP as the original host. If this is not the desired behavior the recovery system should be booted in isolation and reconfigured after logging in with the **Recover** `<hostname>` boot option.
- If multiple restores are performed using the same temporary IP, the temporary IP must first be deleted from Rubrik CDM under **Servers & Apps -> Linux and Unix Servers** and re-added upon each reuse.
- Relax-and-Recover's **ldd** check of other binaries or libraries may result in libraries not being found. This can generally be worked around by adding the path to those libraries to the `LD_LIBRARY_PATH` variable in `/etc/rear/local.conf`. Do this by adding the following line in `/etc/rear/local.conf`:

```
export LD_LIBRARY_PATH="$LD_LIBRARY_PATH:<path>"
```

- To make CentOS v7.7 work the following line was needed:

```
export LD_LIBRARY_PATH="$LD_LIBRARY_PATH:/usr/lib64/bind9-export"
```

- To make CentOS v8.0 work the following line was needed:

```
export LD_LIBRARY_PATH="$LD_LIBRARY_PATH:/usr/lib64/bind9-export: \
/usr/lib64/eog:/usr/lib64/python3.6/site-packages:/usr/lib64/samba: \
/usr/lib64/firefox"
```

- Rear may not set the static IP on a system when the ISO boots. To workaround this set the following in `/etc/rear/local.conf`:

¹⁴ <https://github.com/rear/rear>

¹⁵ <http://relax-and-recover.org/documentation/installation>

```
# Specify networking commands to reset static IP if the ReaR ISO doesn't boot with a
# static IP address
NETWORKING_PREPARATION_COMMANDS=( 'ip addr add <STATIC_IP_ADDRESS> dev eth0' \
'ip link set dev eth0 up' \
'route add -net <LOCAL_SUBNET>>/<LOCAL_SUBNET_PREFIX/MASK> eth0' \
'route add default gw <DEFAULT_GATEWAY>' 'return' )
```

See <https://github.com/rear/rear/blob/master/usr/share/rear/conf/default.conf>¹⁶ for more details on these options.

- When using the Rubrik CDM integration on virtual systems with 1GB of RAM, the recovery system may experience a kernel panic during boot. This can be worked around by increasing the RAM to 2GB.

TROUBLESHOOTING

If Relax-and-Recover is failing use the following troubleshooting tips to isolate the problem:

- Verify that Relax-and-Recover will recover the Linux system without using the CDM backup and restore method. Most errors are due to configuration with Relax-and-Recover itself and not Rubrik CDM. Use the default Relax-and-Recover backup and restore method to test this.
- Follow the OS specific configuration guides as mentioned at the beginning of this document.
- Example configurations for specific operating systems can be found in these links:
 - Red Hat
https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/6/html/deployment_guide/ch-relax-and-recover_rear
 - Ubuntu
<http://manpages.ubuntu.com/manpages/disco/en/man8/rear.8.html>
 - SUSE
https://en.opensuse.org/SDB:Disaster_Recovery
<https://documentation.suse.com/sle-ha/15-SP1/html/SLE-HA-all/cha-ha-rear.htm>
 - Generic
<https://github.com/rear/rear>

NOTE: Ignore any instructions to configure external storage like NFS, CIFS/SMB or ftp. Also ignore any instructions to configure a specific backup method. This will be taken care of in the next steps.

NOTE: Ignore any instructions to schedule ReaR to run via the host based scheduler (cron). Rubrik CDM will run ReaR via a pre-script in the fileset. If this is not preferred ReaR can be scheduled on the host, however, the ISOs created may not be in sync with the backups.
